Самостійне електронне текстове мережеве видання

Econometrics : practicum for Bachelor's (first) degree students E42 of all specialities [Electronic resource] / compiled by L. Guryanova, S. Prokopovych, S. Milevskiy. - Kharkiv : S. Kuznets KhNUE, 2018. 82 p. (English)

The basic questions of analysis and forecasting of socio-economic and financial processes and systems through the application of econometric methods and models are presented. The practicum on the academic discipline with the use of the software Microsoft Excel is provided.

For students of all specialities.

## The general information

The practicum is intended for students to assimilate the theoretical and practical material, acquire skills in the use of application packages to ensure the construction and study of different types of models, and expand students' knowledge of the application of mathematical modeling to economic calculation, prediction, and analysis of economic systems.

Microsoft Excel is proposed to be used for practical activities. This package contains a set of statistical methods that support solutions to various econometric problems. Microsoft Excel was developed to work with in Windows. The practical tasks were developed on the assumption that students are familiar with the basic principles and methods of work in Windows.

Each practical task is considered as an example for solving some problems with detailed comments and pictures. It is recommended that practical task should be performed consistently as the steps and techniques are common and will be described only once. In addition, consistent performance helps better learn the material and consolidate the knowledge of the academic discipline.

The practical tasks deal with the main topics and subjects based on the theoretical material of the relevant topics as well as previous issues. Each activity contains goals and tasks to be performed and guidelines for doing them.

To confirm the results of the practical activity students should prepare individual reports that include: the basic data for solving the problem, formulation of the problem, printing the main results of building the model, analysis of calculations and findings. The variant number, the full name of the student who performed the work and the full name of the teacher who assessed the report should be indicated on the title page.

The mark for the work depends on the practical activity results and the way it has been presented. Special attention is paid to the knowledge of the theory, correctness and completeness of the findings of the economic interpretation of the results.

# Content module 1 <br> The basics of econometric modeling 

## Practical activity 1. Preliminary analysis of baseline data

The goal is to consolidate the theoretical and practical material, acquire the skills in working with the Descriptive Statistics function of the Data Analysis add-in in the MS Excel package.

The task is to analyze the variation series for the sampled data of Ukrainian banks using the Descriptive Statistics function in the Data Analysis module in the MS Excel package.

1. Calculate the statistical characteristics of the series (the mean, the variance, the mean square deviation, the modal value, the median, the range of variation, the asymmetry and excess coefficients).
2. Construct a histogram and a random value distribution polygon, draw conclusions about the nature of the distribution law.
3. Test the hypothesis of a normal distribution law using the Kolmogorov Smirnov and Pearson criteria.
4. Draw conclusions about the grouping of banks based on the size of the relevant indicator.
5. Identify abnormal observations, remove them from the sample and repeat all the previous stages of the study.
6. Compare two samples. Draw conclusions.

## Guidelines

For the solution and analysis of this type of tasks, MS Excel provides the Data Analysis add-in. Let's consider the order of work in this add-in.
1.1. Launching MS Excel and data preparation. Select the MS Excel program in the application menu, after entering it, enter the baseline data as shown in Fig. 1.1.

In order to facilitate the analysis of the baseline data for their dimension in the Income column, select the data, the Cell / Numerical Format for them, and the Bulk Batch Separator check box (Fig. 1.2).

### 1.2. Starting Data Analysis add-in. Click the Data tab, click the Data

 Analysis button.If the Data Analysis button is unavailable, you need to install the Add-in Analysis Package.

To do this, on the File tab, click Parameters, and then the Add-ins category. In the Management list, click Excel Extras, and then click Go (Fig. 1.4).

Fig. 1.4. Add-ins Management in MS Excel

In the Available Add-ins window, select the Analysis Package check box, and then click OK (Fig. 1.5).

Fig. 1.5. Selecting the Analysis Package
If the Analysis Package item is not listed in the Available Add-ins list, click Browse to find the add-in.

If you receive a message that the Analysis Package add-in is not installed on your computer, click the Yes button to install it.

After clicking the Data Analysis button on the Data tab, a window with a list of available features will appear. Select Descriptive Statistics and click OK (Fig. 1.6).

Fig. 1.6. Selecting the function

In the window that appears, select the output range (Fig. 1.7).

Fig. 1.7. Selecting the source data
Click OK and you will receive the results in a new sheet (Fig. 1.8).

|  | A | B |
| :---: | :--- | ---: |

| 14 | Sum | 17456457 |
| 15 | Count | 25 |

Fig. 1.8. The results of the descriptive statistics calculation for a discrete series

The following characteristics are obtained:
Mean - the mean value - a generalized indicator that characterizes the typical (averaged) values of the options for the totality of objects under investigation;

Standard Error - the standard error of the mean - the value that characterizes the standard deviation of the sample mean, calculated on the sample size $n$ from the general data set. The magnitude of the standard error depends on the variance of the general data set and the sample size $n$. Since the variance of the general data set is usually unknown, the estimate of the standard error is calculated by the formula:

$$
\begin{equation*}
S E_{\bar{x}}=\frac{s}{\sqrt{n}}, \tag{1}
\end{equation*}
$$

where $s$ is standard deviation of the random variable based on the unbiased estimation of its sample dispersion;
$n$ is the sample size;
Median - the median which is an option that characterizes the center of variation;

Mode - the modal value - which is the variant that most often occurs in the studied set of objects;

Standard Deviation - the standard deviation which is a measure of dispersion relative to the aggregate average;

Sample Variance - the unbiased sample variance estimation - an indicator that reflects the fluctuations of each option relative to its mean;

Kurtosis - the asymmetry coefficient characterizing the asymmetry of the distribution: if $K_{a}>0$, then there is a right-side asymmetry, if $K_{a}<0$, then it is left-side;

Skewness - the coefficient of excess characterizing the height of the distribution peak: if $K_{b}>0$, there is a high vertex distribution, if $K_{b}<0$, the vertex is flat;

Range - the sampling range;
Minimum - the minimum value;
Maximum - the maximum value;
Sum - the sum of all sample options;
Count - the number of observations (sample items).
Copy these characteristics to the sheet with the initial data.
2. Construction of a distribution polygon. To illustrate the representation of a discrete series, it is necessary to construct a distribution graph. The graphical representation of the discrete variation series, where the objects under investigation are located along the $O X$-axis, and the $O Y$-axis is the value of the option, is called the distribution polygon (Fig. 1.9).

Fig. 1.9. The distribution polygon
3. Construction of an interval series. To transform a discrete series to an interval one, you need to calculate the step of grouping:

$$
\begin{equation*}
k=\frac{\max (x)-\min (x)}{1+3.32 \log _{10} N} \tag{2}
\end{equation*}
$$

where $\max (x)$ is the maximum value of the discrete variation series;
$\min (x)$ is the minimum value of the discrete variation series;
$\max (x)-\min (x)$ is the range of the variation series;
$N$ is the number of observations;
$1+3.32 \log _{10} N$ is the number of intervals.
In the example that we are considering, we form $1+3.32 \log _{10} N=5.64 \approx 6$ intervals with the grouping step equal to $k=\frac{11839530}{6}=1973255$.

The next step in the formation of an interval series is the definition of the upper and lower limits of intervals: the lower limit of the first interval is the minimum value of the variation series, the upper limit of the interval is calculated as the sum of the value of the lower limit and the step of grouping; the lower limit of the next interval is the value of the upper limit of the previous interval, etc. Calculations are carried out until the maximum value of the variation series is covered by the last interval. The formulas for calculation are shown in Fig. 1.10, and the results are presented in Fig. 1.11.

Fig. 1.11. The results of the calculation of the interval limits

To complete the formation of an interval series, it is necessary to determine the frequency of occurrence of values in the corresponding interval, using the function: FREQUENCY (array of data, array of intervals).

To do this, you need to select the entire range of cells, which will calculate the frequencies (in this case D32: D37), write the "=" sign and enter the FREQUENCY () function, as shown in Fig. 1.12.

Fig. 1.12. The formula for calculating the empirical frequencies of an interval series

Then, at the same time, press the three Shift + Ctrl + Enter buttons. Then the whole array of frequencies will be output on a sheet. The results of calculating the empirical frequencies and some other intermediate calculations are shown in Fig. 1.13.

Fig. 1.13. The results of the interim calculations
Below, the results of calculations of the basic statistical characteristics of the interval series are shown.

The average value:

$$
\begin{equation*}
\bar{x}=\frac{\sum x_{i} f_{i}}{\sum f_{i}}=\frac{35412988}{25}=1146519.5 . \tag{3}
\end{equation*}
$$

In the next step, you need to perform some more intermediate calculations, the results of which are shown in Fig. 1.14.

| $\square$ | D | E | F | G | H |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 31 | Empirical frequencies (f) | Middle of the interval (x) | x-f | $(x-\bar{x})^{2} \cdot f$ | $(x-X)^{4} \cdot f$ |
| 32 | 24 | 1021868,5 | 24524844 | 3737985883224 | 5,82189E+23 |
| 33 | 0 | 2995 123,5 | 0 | 0 | 0 |
| 34 | 0 | 4968378,5 | 0 | 0 | 0 |
| 35 | 0 | 6941633,5 | 0 | 0 | 0 |
| 36 | 0 | 8914888,5 | 0 | 0 | 0 |
| 37 | 1 | 10888 143,5 | 10888144 | 89711661197376 | 8,04818E+27 |
| 38 | 25 |  | 35412988 | 93449647080600 | $8,04876 \mathrm{E}+27$ |

Fig. 1.14. The interim calculations
Now you can calculate the following characteristics of the interval series. The dispersion:

$$
\begin{equation*}
D(x)=\frac{\sum\left(x_{i}-\bar{x}\right)^{2} f_{i}}{\sum f_{i}}=\frac{93449647080600}{25}=3737985883224 . \tag{4}
\end{equation*}
$$

The standard deviation:

$$
\begin{equation*}
S(x)=\sqrt{D(x)}=\sqrt{3737985883224}=1933387.2 \tag{5}
\end{equation*}
$$

The modal value: to calculate this characteristic you need to define the modal interval. A modal interval is the interval with the highest frequency (in the example, it is the first interval). Therefore,

$$
\begin{gather*}
M_{o}=\frac{f_{m o}-f_{m o-1}}{\left(f_{m o}-f_{m o-1}\right)+\left(f_{m o}-f_{m o+1}\right)} \cdot k+x_{m o}=  \tag{6}\\
=\frac{24-0}{(24-0)+(24-0)} \cdot 1973255+35241=1021868.5,
\end{gather*}
$$

where $f_{m o}$ is the frequency of the modal interval;
$f_{m-1}$ is the frequency of the interval preceding the modal;
$f_{m+1}$ is the frequency of the interval following the modal;
$k$ is the intervals' grouping step;
$x_{m o}$ is the lower bound of the modal interval.
The median: to calculate this characteristic, it is necessary to determine the median interval. The median interval is the interval that covers the half-
sum of all frequencies, that is to determine the median, it is necessary to calculate the half-sum of all frequencies $N_{m e}=\frac{\sum f_{i}}{2}=\frac{25}{2}=12.5$ and the accumulated frequencies of each interval (Fig. 1.15).
$\left.\begin{array}{|c|c|c|}\hline 4 & \begin{array}{c}\mathrm{D} \\ \\ 31\end{array} & \begin{array}{c}\text { Empirical } \\ \text { frequencies } \\ (\mathrm{f})\end{array}\end{array} \begin{array}{c}\text { Cumulative } \\ \text { frequencies } \\ (\mathrm{S})\end{array}\right]$

Fig. 1.15. Calculation of the accumulated frequencies
In the example, half-sum of all the frequencies covers the first interval. Therefore,

$$
\begin{gather*}
M_{e}=\frac{N_{m e}-S_{m e-1}}{f_{m e}} \cdot k+x_{m e}=  \tag{7}\\
=\frac{12.5-0}{24} \cdot 1973255+25241=1062978.0,
\end{gather*}
$$

where $f_{m e}$ is the frequency of the median interval;
$S_{m e-1}$ is the cumulative (accumulated) frequency of the interval preceding the median;
$N_{m e}$ is the half-sum of all the frequencies;
$k$ is the intervals' grouping step;
$x_{m e}$ is the lower boundary of the median interval.
The asymmetry coefficient:

$$
\begin{equation*}
K_{a}=\frac{\bar{x}-M_{0}}{S(x)}=0.204 \tag{8}
\end{equation*}
$$

Because, $K_{a}>0$, there is a right-side asymmetry.
The coefficient of excess (for interim calculations, see Fig. 1.14):

$$
\begin{equation*}
K_{e}=\frac{1}{\sum f_{i}} \cdot \frac{\sum\left(x_{i}-\bar{x}\right)^{4} f_{i}}{(S(x))^{4}}=23.042 \tag{9}
\end{equation*}
$$

Because $K_{e}>0$, we conclude that there is a high vertex distribution.
The results of the calculation of the interval series characteristics are shown in Fig. 1.16.

| 4 | A | B | C |
| :---: | :---: | :---: | :---: |
| 40 | Interval series |  |  |
| 41 |  | Mean | 1416519,5 |

| 45 |  | Median | 1062 978,0 |
| 46 |  | Kurtosis | 0,204124145 |
| 47 |  | Skewness | 23,042 |

Fig. 1.16. The results of the calculations of the interval series characteristics

The graphic representation of the interval series is the distribution histogram (Fig. 1.17).

Fig. 1.17. The distribution histogram
4. Checking the sample for the normal distribution law. Further analysis involves checking the sample for the normal distribution law based on the Pearson and Kolmogorov - Smirnov criteria.

A prerequisite for determining the nature of the distribution law is the calculation of theoretical frequencies corresponding to the normal distribution law:

$$
\begin{equation*}
f^{\prime}(t)=\frac{n \cdot k}{S(x)} \cdot \varphi(t), \tag{10}
\end{equation*}
$$

$$
\begin{gather*}
\varphi(t)=\frac{1}{\sqrt{2 \pi}} \cdot e^{-\frac{t^{2}}{2}}  \tag{11}\\
t=\frac{x-\bar{x}}{S(x)} \tag{12}
\end{gather*}
$$

where $f^{\prime}(t)$ is the theoretical frequencies corresponding to the normal distribution law,
$x_{i}$ is the value of the $i$ variable;
$\bar{x}$ is the average value;
$S(x)$ is the standard deviation;
$n$ is the number of observations;
$k$ is the grouping step.
For further calculations, you need to create a new table with empirical frequencies and mid-intervals. To determine the Gauss function $\varphi(t)$, you need to use the formula NORM.DIST (x; mean; standard_dev; integral), which returns the normal distribution function for the specified mean and standard deviation. So, for the first interval, in the cell D50, enter the formula $=1-$ NORM.DIST(C50;\$C\$41;\$C\$43;1), as shown in Fig. 1.18.

| 40 |  | Mean | =F38/D38 |  |  |  |

Fig. 1.19. The results of the calculation of the theoretical and accumulated theoretical frequencies

To determine the nature of the distribution law and its compliance with the normal law, the Pearson criterion is most often used, calculated by the formula:

$$
\begin{equation*}
\chi^{2}=\sum \frac{\left(f-f^{\prime}\right)^{2}}{f^{\prime}} \tag{13}
\end{equation*}
$$

where $f$ is the empirical frequencies;
$f^{\prime}$ is the theoretical frequencies.
The estimated value of the criterion must be compared with the critical one, which is in a special table and depends on the accepted probability and the number of degrees of freedom ( $k=m-3$, where $m$ is the number of intervals). If $\chi^{2} \leq \chi_{t a b}^{2}$, then the difference between the empirical and theoretical frequencies can be considered random and the hypothesis regarding the normal distribution law cannot be rejected.

The Kolmogorov - Smirnov criterion is used for determining the maximum difference between the frequencies of the empirical and theoretical distribution:

$$
\begin{equation*}
\lambda=\frac{D}{\sqrt{\sum f}} \tag{14}
\end{equation*}
$$

where $D=\left|S-S^{\prime}\right|$ is the maximum difference between the accumulated empirical and theoretical frequencies,
$\sum f$ is the sum of empirical frequencies.
The estimated value of the criterion is used to find the probability of adopting a hypothesis regarding the normal distribution law. The greater the
probability value, the greater the probability that the discrepancies between the empirical and theoretical frequencies are random.

Fig. 1.20 shows the results of the intermediate calculations and the estimated values of the Pearson and Kolmogorov - Smirnov criteria.

Fig. 1.20. The calculated values of the Pearson and Kolmogorov - Smirnov criteria

Comparing the obtained values with the tables, we can conclude that the differences between the empirical and theoretical distribution are significant, so the hypothesis regarding the normal law of the distribution of the random variable should be discarded.

Thus, this sample is not homogeneous and close to normal distribution. This means that it cannot be used as a source for building an econometric model, and it needs to be refined.
5. Removal of abnormal observations. An anomalous observation, that is, such that is not typical of this sample, can be detected by means of analysis of the distribution polygon (see Fig. 1.9) or distribution histogram (see Fig. 1.17). There is at least one such observation - Privatbank. It has an income that exceeds dozens of times all other observations and should be excluded from the sample.

Copy all data except Privatbank to a new sheet and repeat all the previous steps of the study.

Compare the characteristics of both samples, draw conclusions.

## Practical activity 2. Modeling and analysis of simple linear econometric models

The goal is to consolidate the theoretical and practical material, to acquire the skills in modeling and analysis of simple econometric models in the Data Analysis add-in of Microsoft Excel.

The task is to verify the existence of linear dependence between the given indicators in the Data Analysis add-in of Microsoft Excel.

1. Build a linear econometric model and define all its specifications (the parameters of the model, the standard deviations of the parameters of the model, the variance and standard deviation of the error of the model, the correlation and determination coefficients).
2. Verify the statistical significance of parameters and the correlation coefficient using the Student's t-test. Verify the adequacy of the model with the Fisher test.
3. Calculate theoretical values of the dependent variable and errors of the model, construct a graph of the linear function with confidence intervals, construct a histogram and a graph of the distribution of errors, grouping of data depending on the values of errors, and provide economic interpretation of the grouping.
4. Calculate the predicted values of the dependent variable and the confidence intervals if the values of the independent parameter are provided.
5. Draw conclusions about the adequacy of the constructed model, provide economic interpretation of the dependence and the possibility of its theoretical use.

## Guidelines

For the construction and analysis of simple linear econometric models, the Data Analysis add-in is provided in Microsoft Excel. Let us examine the order of work in the module.

## 1. Launching MS Excel and data preparation.

After starting Microsoft Excel, the input data of the model should be entered, as shown in Fig. 2.1.

|  | A | B | C | D | E |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | $i$ | $X_{i}$ | $Y_{i}$ |  |  |
| 2 | 1 | 73 | 0,5 |  |  |
| 3 | 2 | 85 | 0,7 |  |  |
| 4 | 3 | 102 | 0,9 |  |  |
| 5 | 3 | 115 | 1,1 |  |  |
| 6 | 5 | 122 | 1,4 |  |  |
| 7 | 6 | 126 | 1,4 |  |  |
| 8 | 7 | 134 | 1,7 |  |  |
| 9 | 8 | 147 | 1,9 |  |  |
| 10 |  |  |  |  |  |
| 11 |  |  |  |  |  |

Fig. 2.1. The input data

## 2. Calculations.

In order to start calculations, it is necessary to select the menu item Data / Data Analysis (Fig. 2.2). After selection of the Regression tool of the module, a dialog box of the module will appear where variables for analysis can be set (Fig. 2.3).

Fig. 2.2. Selecting the module

Fig. 2.3. The dialog box of the regression tool
Select the range of input variables $X$ and $Y$ (if the names of the variables are required with their initial values, the Labels option must be selected). If $a_{0}$ equals zero, the Constant is Zero option must be set. In the module, there is also a possibility to change the confidence level of the model with the Confidence Level option that by default equals $95 \%$.

In the next block of the dialog box, the output destination can be chosen. There are three options: 1) the range selected by the user (Output Range); 2) a new worksheet of the same file (New Worksheet Ply); 3) a new MS Excel file (New Workbook).

In the last block of the dialog box, the Residuals and Residual Plots options, that are necessary for analysis, must be chosen.

Once the selection is confirmed by pressing $O K$, the results of modeling will appear in the new worksheet of the same file (Fig. 2.4).

## 3. Analysis of the model, definition of its specifications, verification of the adequacy and statistical significance of the model.

Developing a linear econometric model and defining all of its specifications. The parameters received during estimation of the model are given in the third table from the top (Fig. 2.5).

Fig. 2.4. The modeling results

|  |  | Standard |  |  |  |  |
| :--- | ---: | ---: | :---: | :---: | :---: | :---: |
| 16 |  | Coefficients | Error | t Stat | P-value | Lower 95\% | Upper 95\% 6 (

Fig. 2.5. The results (parameters) of the model estimation
In the first column of the table (Fig. 2.5), model parameters $a_{0}$ (Intercept) and $a_{1}\left(X_{1}\right)$ are given. Thus, the theoretic model is as follows:

$$
\begin{equation*}
Y=-0.973875115+0.019237833 \cdot X_{1} . \tag{15}
\end{equation*}
$$

The next columns relate to the analysis of the statistical significance of the model parameters, namely, Std Error refers to $\sigma_{a 0}$ and $\sigma_{a 1}$ respectively; $t$ Stat and $P$-values are the corresponding values of the Student's t-test for
each parameter and the probability level of the error of accepting the hypothesis. The values of the latter are as follows $t_{a 0}=-6.236584132$ and $t_{a 1}=14.2149647$. Both calculated values of the Student criterion exceed the tabulated one $t_{t a b l}=2.447$ in their absolute values, which indicates the statistical significance of both parameters (the tabulated value of this criterion can be obtained with the $\operatorname{TINV}(0.05,6)$ function, where the first number is the probability of the error level, and the second one is the number of degrees of freedom).

The last two columns contain the values of the interval estimates of each model parameter with the probability level of $95 \%$.

Let us analyze the results of the adequacy analysis of the overall model presented in the first table of the results (Fig. 2.6).

| Regression Statistics |  |
| :--- | :--- |
| Multiple R | 0.985475971 |
| R Square | 0.971162888 |
| Adjusted R Square | 0.966356703 |
| Standard Error | 0.089321148 |
| Observations | 8 |

Fig. 2.6. The adequacy analysis of the overall model as part of the results of the model estimation

Multiple $R$ is the multiple correlation coefficient (in the case of simple linear regression it equals the bivariate correlation coefficient between $X$ and $Y$ );
$R$ Square is the coefficient of determination of the model;
Adjusted $R$ Square is the coefficient of determination adjusted by the number of observations and the number of model parameters;

Standard Error is the standard deviation of the model errors; this statistic is a measure of scatter of the values relative to the regression line $\left(\sigma_{e}\right)$;

Observations correspond to the number of initial observations.
The results of the analysis of variance of the model are shown in the second table of the regression results (Fig. 2.7).

| ANOVA | $d f$ | SS | MS | $F$ | Significance F |
| :--- | :--- | :--- | :---: | :---: | :--- |
| Regression | 1 | 1.612130395 | 1.612130395 | 202.0652216 | $7.57632 \mathrm{E}-06$ |
| Residual | 6 | 0.047869605 | 0.007978268 |  |  |
| Total | 7 | 1.66 |  |  |  |

Fig. 2.7. The analysis of variance

The table contains the sum of squares (SS) and variance (MS) for regression and for errors, and the Fisher's test.

The calculated value of the Fisher's test significantly exceeds its tabulated values $F_{\text {tabl }}(0.05,1,6)=5.987$, indicating the statistical significance of the overall model (the tabulated value of this test can be obtained with the $\operatorname{FINV}(0.05,1,6)$ function, where the first number is the level of probability of error, and the last two are the numbers of degrees of freedom).

Thus, the values of these coefficients indicate a rather high level of quality and adequacy of the model, which makes it possible to use the model for forecasting.

## 4. Analysis of errors.

The theoretical values of the dependent variable and the error of the model are shown in the last table of the results (Fig. 2.8).

| Observation | Predicted $Y$ | Residuals |
| :--- | :--- | :--- |
| 1 | 0.430486685 | 0.069513315 |
| 2 | 0.66134068 | 0.03865932 |
| 3 | 0.988383838 | -0.088383838 |
| 4 | 1.238475666 | -0.138475666 |
| 5 | 1.373140496 | 0.026859504 |
| 6 | 1.450091827 | -0.050091827 |
| 7 | 1.60399449 | 0.09600551 |
| 8 | 1.854086318 | 0.045913682 |

Fig. 2.8. The analysis of errors of the model
The scatter plot of the model errors is depicted in Fig. 2.9.
X 1 Residuals

Fig. 2.9. The residuals scatter plot of the model
For visual verification of frequency distribution of errors by the normal probability law, errors should be grouped in advance, i.e. their variation distribution should be transferred to the normal probability plot (see the Guidelines for laboratory work 1).

The intermediate calculations and the resulting interval series of errors are represented in Fig. 2.10 and 2.11.

## 5. The graph of a linear function with confidence intervals.

In order to construct a linear function with confidence intervals, first of all, it is necessary to move the theoretical values of $Y$, the value of the mean square error $\sigma_{e}$, the table value of Student's statistics from the page with the results to the page with the input data and calculate the average value of $X$, as shown in Fig. 2.13.

| 4 | A | B | C | D |
| :---: | :---: | :---: | :---: | :---: |
| 1 | $i$ | $X_{i}$ | $Y_{i}$ | Predicted $Y_{i}$ |
| 2 | 1 | 73 | 0,5 | 0,4305 |
| 3 | 2 | 85 | 0,7 | 0,6613 |
| 4 | 3 | 102 | 0,9 | 0,9884 |
| 5 | 4 | 115 | 1,1 | 1,2385 |
| 6 | 5 | 122 | 1,4 | 1,3731 |
| 7 | 6 | 126 | 1,4 | 1,4501 |
| 8 | 7 | 134 | 1,7 | 1,6040 |
| 9 | 8 | 147 | 1,9 | 1,8541 |
| 10 |  |  |  |  |
| 11 | $\bar{X}$ | 113 | $\sigma_{e}$ | 0,089321 |
| 12 |  |  | $t$ table | 2,447 |

Fig. 2.13. The initial view of the page with the input data

The next step is to calculate the value $\Delta Y$ for each of the values of the independent variable $X$ by the formula:

$$
\begin{equation*}
\Delta Y_{p r}=t_{t a b l} \cdot \sigma_{e} \cdot \sqrt{\frac{1}{n}+\frac{\left(X_{i}-\bar{X}\right)^{2}}{\sum_{i=1}^{n}\left(X_{i}-\bar{X}\right)^{2}}}, \tag{16}
\end{equation*}
$$

and identify the lower $\left(\hat{Y}_{i}-\Delta Y_{p r}\right)$ and upper $\left(\hat{Y}_{i}+\Delta Y_{p r}\right)$ boundaries of the interval series for the theoretical values of $Y$. The formulas for calculation are given in Fig. 2.14.

Fig. 2.15. The results of the calculation of the interval values of $\boldsymbol{Y}$
Getting all the necessary results makes it possible to start constructing the graph. After selecting the desired type of graphics Spot, we turn to the
definition of the data series，including：the actual value of $Y$ ，the theoretical （predictive）value of $Y$ ，the lower boundary of the theoretical（predictive）value of $Y$ ，the upper boundary of the theoretical（predictive）value of $Y$ ．

Fig．2．16．Selection of the data series for plotting
The values of $X$ should be chosen as the values of the horizontal axis （Fig．2．17）．

Fig．2．17．Selection of the initial data for plotting
After the final formatting of some series of data（namely：the image graphs of the theoretical values of $Y$ according to interval estimates dashed line through the Data series format／Line type）we obtain a graph of the linear function with confidence intervals（Fig．2．18）

Fig. 2.18. The graph of the linear function with confidence intervals
As shown in Fig. 2.18 almost all the actual values of $Y$ lie on the line corresponding to the theoretical model, confirming its high quality.
6. Calculation of predicted values of the dependent variable and confidence intervals of change.

As the model is adequate, its parameters are significant, the model can be used for forecasting. In order to calculate the predicted values of the dependent variable, it is necessary to add an additional line with the predicted values of $X$ to the initial data, and calculate the theoretical (predicted) point value of $Y$ using the model with point values of parameters, $\Delta Y p r$ by the formula (16), and the interval predicted value (Fig. 2.19).

| 13 | $X_{i}$ | 0,01924 |  |  |  |  | $\Sigma$ | 4356 |

Fig. 2.19. Calculation of the predictive value of $Y$ with confidence intervals

Thus, if $X_{p r}=140$, we get:

$$
\begin{equation*}
1.601 \leq Y_{p r} \leq 1.838 . \tag{17}
\end{equation*}
$$

## Practical activity 3. Building and analysis of multiple linear econometric models. Multicollinearity

The goal is to consolidate the theoretical and practical material on the topics "Multiple linear regression" and "Multicollinearity", to acquire the skills in modeling and analysis of multifactorial econometric models in Microsoft Excel.

The task is to verify the existence of linear multiple connection between the coincident indicators in the Data Analysis add-in of Microsoft Excel.

1. Build a linear multifactorial econometric model (include all the coincident factors) and determine all its characteristics the (parameters of the model, the mean square deviation of the parameters of the model, the dispersion and the mean square deviation of errors of the model, the coefficients of multiple correlation and determination) with the help of the Data Analysis add-in in Microsoft Excel.
2. Check the statistical significance of the model parameters. Check the model's adequacy with the help of the Fisher's criterion.
3. Adduce tables with the theoretical values of the dependent indicator and the values of the model's errors. Build a graph of the linear function. Build a histogram and a graph of the distribution of errors. Adduce grouping of data depending on the values of errors, give economical interpretation.
4. Find the forecasted value of the dependent variable $Y_{p r}$ and the confidential intervals if there is available data about the future values of independent indicators ( $X_{1 p r}, X_{2 p r}, X_{3 p r}$ ).
5. Adduce a matrix of pair correlations for factorial features. Check the model for presence of multicollinearity (tight linear connection) between the factorial variables with the help of the Farrar - Glauber algorithm.
6. Exclude from the model the factors which have the least influence on the dependent variable or are interconnected with each other (use the results of the Student's criterion, the Farrar - Glauber algorithm and the coefficients of pair correlations). Determine all characteristics of a new regression; draw conclusions about its adequacy.

## Guidelines

## 1. Launching Microsoft Excel and preparation of data.

Let's consider that there is available information about the values of the dependent variable $y$ (GNP, mIn UAH) and the independent variables: $x_{1}$ (labor resources expenditures, mln UAH), $x_{2}$ (basic funds expenditures, mln UAH), $x_{3}$ (flow-out of capital to the off-shore zone, mln UAH). After launching Microsoft Excel enter the initial data as shown in Fig. 3.1.

|  | A | B | C | D | E |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | № | $y$ | $x_{1}$ | $x_{2}$ | $x_{3}$ |
| 2 | 1 | 51,2 | 9,8 | 6,8 | 0,65 |
| 3 | 2 | 54,7 | 10,1 | 10,5 | 0,82 |
| 4 | 3 | 65,6 | 10,9 | 12,2 | 1,04 |
| 5 | 4 | 53,3 | 10,4 | 12,8 | 1,53 |
| 6 | 5 | 72,7 | 12,1 | 13,4 | 1,94 |
| 7 | 6 | 75,7 | 12,8 | 13,8 | 1,75 |
| 8 | 7 | 85,6 | 13,2 | 14,4 | 1,99 |
| 9 | 8 | 91,5 | 13,6 | 14,6 | 0,92 |
| 10 | 9 | 96,7 | 12,3 | 16,5 | 0,95 |
| 11 | 10 | 102,6 | 13,5 | 18,2 | 0,9 |

Fig. 3.1. The initial data
2. Building a linear multifactorial econometric model and determining all its characteristics with the help of the Data Analysis add-in in Microsoft Excel.

The parameters of linear multifactorial models and all their characteristics can be determined with the help of the Data Analysis/Regression add-in, the same way as for pair regression (see the guidelines for laboratory work 2), but choosing three adjoining columns $x_{1}, x_{2}, x_{3}$ as the output massive $X$, as shown in Fig. 3.2.

The results of building the multifactorial model are presented in Fig. 3.3.
The received model looks like:

$$
\begin{equation*}
\hat{y}=-46.6275+8.6025 \cdot x_{1}+2.3788 \cdot x_{2}-9.7758 \cdot x_{3} \tag{18}
\end{equation*}
$$

As can be seen in Fig. 3.3, the values of the coefficients of the model's adequacy (a more detailed description of which is given in the guidelines to practical activity 2 ) are quite high. The statistical significance of the model's parameters by the Student's criterion is: all parameters are significant $\left(\mathrm{t}_{\text {tabl }}(0.05 ; 6)=2.447\right)$.

| $\mathbf{A}$ | A | B | C | D | E |
| :---: | :---: | :---: | :---: | :---: | :---: |

| 10 | 104,0024161 | $-1,402416$ |

Fig. 3.3. The results of building the multifactorial model with the help of the Data Analysis/Regression add-in

## 3. Building a graph of the linear function.

To build a graph, it is necessary to copy the factual values of $Y$ from the main window, and the theoretical values of $\hat{Y}$ (the column Predicted $Y$ ) from the window with the results of building a regression. Then, in the tab Insert, choose Graph / Graph with markers and enter the input data for building a graph. The result of building such a graph is presented in Fig. 3.4 (for the range of the factual values of $Y$ the type of diagram was changed into Dotted).

Fig. 3.4. The results of building a multifactorial model with the help of the Data Analysis/Regression add-in

So, the factual and theoretical values of the dependent variable on the graph (Fig. 3.4) are quite close, which means that the built model is of appropriate quality, but additional analytical procedures are necessary.

## 4. The graphs of the distribution of the model's residuals (errors).

Grouping the errors and building their histogram and the graph of distribution can be realized in the same way as for a simple linear model (see the guidelines to practical activity 2 ). The results of building are presented in Fig. 3.5.

It is seen from the graph of distribution (Fig. 3.5) that the model's errors significantly differ from zero and have quite a wide scope of values, which shows a rather low quality of the built model. Visual analysis of the histogram of the distribution of errors doesn't confirm the normal law of distribution.

Fig. 3.5. The histogram and the graph of the distribution of the model's errors

## 5. The forecasted value of the dependent variable and the confidential

 intervals.Calculation of the forecasted value of the dependent variable can be realized in the same way as in the simple linear model with the difference in the number of independent variables in the model and calculation $\Delta y_{p r}$.

$$
\begin{equation*}
y_{p r}-\Delta y_{p r} \leq \tilde{y}_{p r} \leq y_{p r}+\Delta y_{p r}, \tag{19}
\end{equation*}
$$

where $\Delta y_{p r}=t_{p} \cdot \sigma_{e} \sqrt{X_{p r}^{\top} B^{-1} X_{p r}}$;

$$
X_{p r}^{T}=\left(1, x_{1 p r}, x_{2 p r}, x_{3 p r}\right) .
$$

To get the matrix $B^{-1}=\left(X^{\top} X\right)^{-1}$ it is necessary first to get the matrices $X$ and $X^{\top}$, then to multiply them $\left(X^{\top} X\right)$ and find the inverse matrix $\left(X^{\top} X\right)^{-1}$. All the formulas for calculations are given in Fig. 3.6.

The results of the calculations are presented in Fig. 3.7.
Let's consider that it is necessary to determine the forecasted value of GNP if the forecasted labor resources expenditures are 14 mln UAH, the basic funds expenditures make 17 mln UAH , and the out-flow of capital to offshore zones amounts to 1.5 mln UAH . Then the vector of the forecasted independent variables will look like: $X_{p r}^{\top}(1,14,17,1.5)$.

Fig. 3.7. The results of the calculations
The point estimation of the forecast looks like:

$$
\begin{align*}
\hat{y}=-46.6275+ & 8.6025 \cdot 14+2.3788 \cdot 17-9.7758 \cdot 1.5 \approx \\
& \approx 99.584(\mathrm{~m} \ln \mathrm{UAH}) . \tag{20}
\end{align*}
$$

The formulas for calculating the confidential interval of the forecast are given in Fig. 3.8.

The results of the calculations are presented in Fig. 3.9.
The interval for the forecast looks like:

$$
\begin{align*}
99.5836-7.31677 & \leq \tilde{y}_{p r} \leq 99.5836-7.31677  \tag{21}\\
92.97 & \leq \tilde{y}_{p r} \leq 106.9 .
\end{align*}
$$

Fig. 3.8. The formulas for calculations

Fig. 3.9. The results of the point and interval forecast based on the model

So, in the forecast period, the GNP can be from 92.7 mln UAH to 106.9 mln UAH.

## 6. Assessment of the model's multicollinearity.

To assess the multicollinearity, first of all it is necessary to determine the matrix of pair correlations between all variables. In the Data Analysis addin, choose the option Correlation, whose dialog box after entering the output range of variables looks like in Fig. 3.10.

Fig. 3.10. The dialog box of the tool Correlation
After confirmation of the output options with the $O K$ button, the matrix of pair correlations will appear on a new page, shown in Fig. 3.11.

|  | A | B | C | D | E |  |
| ---: | :---: | ---: | :---: | :---: | :---: | :---: |
| 1 |  | $y$ | $x_{1}$ | $x_{2}$ | $x_{3}$ |  |
| 2 | $y$ | 1 |  |  |  |  |
| 3 | $x_{1}$ | 0,910209 | 1 |  |  |  |
| 4 | $x_{2}$ | 0,887585 | 0,820684 | 1 |  |  |
| 5 | $x_{3}$ | 0,046102 | 0,324931 | 0,227269 | 1 |  |

Fig. 3.11. The matrix of pair correlations between the variables

It is seen in Fig. 3.11, that $Y$ is most influenced by $X_{1}$, and $X_{3}$ almost doesn't have any affect.

We also see, that there is a strong connection between the variables $X_{1}$ and $X_{2}$. This can tell us about the presence of multicollinearity in the model.

Let's check it with the help of the Farrar - Glauber algorithm. The results of the calculation are presented in Fig. 3.12.

The table value of the criterion $\chi^{2}$ with the degrees of freedom $k=0.5 m(m-1)=3$ and the level of significance $\alpha=0.95$ is equal to $\chi_{\text {tabl }}^{2}(\alpha ; 0.5 m(m-1))=7.81$. Because $\chi^{2} \geq \chi_{\text {tabl }}^{2}$, in the array of independent variables there is a general multicollinearity and the research needs to be continued.

Fig. 3.13. The formula for calculating the matrix $\boldsymbol{Z}$
We get the following result:

$$
Z=R^{-1}=\left(\begin{array}{ccc}
3.2650 & -2.5712 & -0.4765  \tag{22}\\
-2.5712 & 3.0794 & 0.1356 \\
-0.4765 & 0.1356 & 1.1240
\end{array}\right)
$$

Next, we should calculate the multiple correlation coefficients $R_{i}$, which characterize the closeness of the connection of each variable with other variables:

$$
\begin{align*}
& R_{1}=\sqrt{1-\frac{1}{z_{11}}}=\sqrt{1-\frac{1}{3.265}} \approx 0.833  \tag{23}\\
& R_{2}=\sqrt{1-\frac{1}{z_{22}}}=\sqrt{1-\frac{1}{3.0794}} \approx 0.822  \tag{24}\\
& R_{3}=\sqrt{1-\frac{1}{z_{33}}}=\sqrt{1-\frac{1}{1.124}} \approx 0.332 \tag{25}
\end{align*}
$$

As we see, the first and second regressors have a close connection with other regressors.

We should also check the statistical significance of the connection of each variable with other variables based on the $F$-criterion:

$$
\begin{align*}
& F_{1}=\frac{\left(z_{11}-1\right)(n-m)}{m-1}=\frac{(3.265-1)(10-3)}{3-1} \approx 7.93 ;  \tag{26}\\
& F_{2}=\frac{\left(z_{22}-1\right)(n-m)}{m-1}=\frac{(3.0794-1) \cdot 7}{2} \approx 7.28 ;  \tag{27}\\
& F_{3}=\frac{\left(z_{33}-1\right)(n-m)}{m-1}=\frac{(1.1240-1) \cdot 7}{2} \approx 0.43 \tag{28}
\end{align*}
$$

The table value of $F$-statistics with the level of significance $\alpha=0.95$ and degrees of freedom $k_{1}=(m-1)=3-1=2$ and $k_{2}=(n-m)=10-3=7$ is equal to $F_{\text {tab }}(0.95 ; 2 ; 7)=4.74$.

Since the calculated values $F_{1}>F_{\text {tab }}$ and $F_{2}>F_{\text {tab }}$, the regressors $X_{1}$ and $X_{2}$ respectively are multicollinear with others.

Next, we find the partial correlation coefficients:

$$
\begin{align*}
& r_{12}^{p}=\frac{-z_{12}}{\sqrt{z_{11} \cdot z_{22}}}=\frac{-(-2.5712)}{\sqrt{3.265 \cdot 3.0794}} \approx 0.811  \tag{29}\\
& r_{13}^{p}=\frac{-z_{13}}{\sqrt{z_{11} \cdot z_{33}}}=\frac{-(-0.4765)}{\sqrt{3.265 \cdot 1.124}} \approx 0.249  \tag{30}\\
& r_{23}^{p}=\frac{-z_{23}}{\sqrt{z_{22} \cdot z_{33}}}=\frac{-(0.1356)}{\sqrt{3.0794 \cdot 1.124}} \approx-0.07 . \tag{31}
\end{align*}
$$

There is a close connection between the regressors $X_{1}$ and $X_{2}$.

It is interesting to compare the obtained values of the partial and pair correlation coefficients. Usually the former are much lower than the latter. But in this case, the partial coefficients that characterize the density of the relationship between the two variables, assuming that the other variables do not affect this relationship, are, in absolute terms, not significantly lower than those of the pairs, moreover for regressors $X_{2}$ and $X_{3}$ there was even a change in the direction of relation from the direct to the reverse. Thus, we can conclude that other variables significantly affect the relationship between the investigated indicators.

Next, we check the statistical significance of the relationship between each of the two variables based on the calculation of the $t$-criterion by the formula:

$$
\begin{align*}
& t_{12}=\left|r_{12}^{p}\right| \frac{\sqrt{n-m}}{\sqrt{1-\left(r_{12}^{p}\right)^{2}}}=|0.811| \cdot \frac{\sqrt{10-3}}{\sqrt{1-(0.811)^{2}}} \approx 3.67  \tag{32}\\
& t_{13}=\left|r_{13}^{p}\right| \frac{\sqrt{n-m}}{\sqrt{1-\left(r_{13}^{p}\right)^{2}}}=|0.249| \cdot \frac{\sqrt{7}}{\sqrt{1-(0.249)^{2}}} \approx 0.68 ;  \tag{33}\\
& t_{23}=\left|r_{23}^{p}\right| \frac{\sqrt{n-m}}{\sqrt{1-\left(r_{23}^{p}\right)^{2}}}=|-0.07| \cdot \frac{\sqrt{7}}{\sqrt{1-(-0.07)^{2}}} \approx 0.193 . \tag{34}
\end{align*}
$$

The estimated values of the $t$-statistic are compared with the tabular ones with degrees of freedom $k=(n-m)=10-3=7$ and the significance level $\alpha=0.95$. Since $t_{12} \geq t_{p}(0.95 ; 7)=2.36$, there is a statistically significant multicollinearity between the independent variables $X_{1}$ and $X_{2}$.

To exclude this negative phenomenon, it is necessary to eliminate the independent variable which has the least influence on the dependent variable $Y$. As we see, such variable is $X_{2}$.

To build a new regression, the raw data should be copied to a new worksheet. Remove the column $X_{2}$, run Data analysis / Regression (Fig. 3.14).

The results of the characteristics of the built new model without $X_{2}$ are shown in Fig. 3.15.

Fig. 3.15. The characteristics of the new model after elimination of multicollinearity

Fig. 3.15 shows that despite the insignificant decrease of coefficients of correlation and determination, in general, the quality of the model has become better after eliminating the variable $X_{2}$, in particular: all parameters of the model are statistically significant, the range of the interval assessments of the parameters and residuals of the model has decreased. So, for forecasting the dependent variable $Y$ it is better to use the model:

$$
\begin{equation*}
\hat{Y}=-65.082+12.8958 \cdot X_{1}-10.4328 \cdot X_{3} . \tag{35}
\end{equation*}
$$

## Content module 2

## Applied econometrics

## Practical activity 4. Testing the residuals for autocorrelation and heteroscedasticity

The goal is to consolidate the theoretical material and to acquire practical skills in testing an econometric model for the presence of autocorrelation and heteroscedasticity of the residuals.

In Table 4.1, the data describing the activities of 22 commercial banks, is presented.

Table 4.1
The initial data

| 11 | 44.4 | 564 | 90.7 | 22 | 84.0 | 960 | 178.8 |

## The task is as follows:

1. Construct a linear multifactorial model, determine all its characteristics (the mean square deviations of the model parameter estimates, the Student criterion, the multiple correlation coefficient, the determination coefficient, the Fisher criterion). Draw conclusions about the statistical significance of the model.
2. Test the residuals of the model for the presence of autocorrelation using the Durbin - Watson criterion, the Von Neumann criterion and the cyclic coefficient of autocorrelation. Draw conclusions. Choose the most appropriate method for estimating the parameters of the econometric model.
3. Test the hypothesis for the presence of heteroscedasticity with the Park, Glaser, White tests. Draw conclusions. Choose the most appropriate method for estimating the parameters of the econometric model.

## Guidelines

Autocorrelation of the residual is the presence of a relationship between the successive elements of a series of the model residuals. Autocorrelation of residuals is most often observed when the econometric model is based on a time series. If there is a correlation between the successive values of some explanatory variable, then the correlation of successive values of the residual will be observed. If the model with autocorrelation of residuals is evaluated by the use of LSMs, then the following negative consequences are possible: the estimation of the model parameters may be unmatched and substantiated but ineffective, i.e., the sample variance of the estimation of $a_{i}$ may be unreasonably large; the statistical criterion $t$ - and $F$-statistics can't be used to verify the model, since the calculation does not take into account the presence of correlations of the residuals; the ineffectiveness of estimations of the parameters of an econometric model usually results in ineffective predictions, that is, the predictive values will have a large sample dispersion.

## 1. Construction of the multiple regression.

With the help of the add-in Data Analysis, tabs Regression on the basis of data in Table 4.1, find the characteristics of the regression equation of the dependence of the banks' income $(y)$ on the number of loan agreements ( $x_{1}$ ) and the authorized capital ( $x_{2}$ ), as shown in Fig. 4.1.

The results of the regression analysis are given in Fig. 4.2.

Fig. 4.1. Calculation of the model parameters using the Data Analysis add-in, the Regression tab

| 18 | X Variable 1 | 1,16901406 | 0,088144 | 13,26252 | 4,7E-11 | 0,984526097 | 1,353502031 |
| 19 | X Variable 2 | 0,08307464 | 0,01558 | 5,332182 | 3,81E-05 | 0,050465622 | 0,115683649 |

Fig. 4.2. The results of the regression analysis
Thus, after applying LSM to the initial data, the following regression equation is obtained:

$$
\begin{equation*}
y=-3.4294+1.17 \cdot x_{1}+0.083 \cdot x_{2}+e ; \quad R^{2}=0.968 ; \quad F=285.282 \tag{36}
\end{equation*}
$$

This equation is statistically significant with the probability 0.95 ( $F_{\text {tab }}=3.52$ ), the relationship between the indicators is very tight. The parameters of the factors are also significant ( $t_{\text {fact }}$ is equal to 13.26 and 5.33 when $t_{t a b}=2.09$ ). Thus, the considered characteristics indicate a high quality of the model. However, conclusions about the significance of the parameters will be reliable, and the model can be used for further analysis and forecast if the analysis of random residuals will not establish a violation of the LSM preconditions.

Here are the model residuals series (Fig. 4.3), obtained using the Data Analysis add-in, the Regression tab (Fig. 4.1).

Fig. 4.3. The model residuals series

## 2. Checking the residual for the presence of autocorrelation.

The most common methods of testing the residuals for the presence of autocorrelation are the Durbin - Watson criterion, the von Neumann criterion, the cyclic coefficient of autocorrelation. Let's consider the essence of these methods.

The Durbin - Watson criterion is based on testing the hypothesis about the existence of autocorrelation between the adjacent residual members
of a series. The statistics that meet this criterion are usually labeled as $d$ or DW and can be calculated by the formula:

$$
\begin{equation*}
d=\frac{\sum_{t=2}^{n}\left(e_{t}-e_{t-1}\right)^{2}}{\sum_{t=1}^{n} e_{t}^{2}} \tag{37}
\end{equation*}
$$

If auto-correlation is missing or small, then the value of $d$ is approximately equal to 2 , while with full autocorrelation the value of $d$ is close to 0 or 4 .

For $d$-statistics critical boundaries have been found that allow us to accept or reject the hypothesis about the presence of autocorrelation. The authors of this criterion estimated the lower $\left(d_{L}\right)$ and upper ( $d_{U}$ ) boundaries with $1 ; 2.5 ; 5 \%$ levels of significance (Fig. 4.4):

1) if $0<d \leq d_{L}$, then the hypothesis about the presence of a positive autocorrelation is accepted;
2) if $d_{L}<d<d_{U}$, then there is no statistical reason to either accept or reject this hypothesis;
3) if $d_{U} \leq d<4-d_{U}$, then the hypothesis about the absence of autocorrelation is accepted;
4) if $4-d_{U}<d<4-d_{L}$, then there is no statistical reason to either accept or reject this hypothesis;
5) if $4-d_{L}<d$ then there is a negative autocorrelation.

| Positive <br> autocorrelation | Uncertainty <br> zone | Autocorrelation is <br> absent | Uncertainty <br> zone | Negative <br> autocorrelation |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | $d_{L}$ | $d_{U}$ | 2 | $4-d_{U}$ | $4-d_{L}$ |

Fig. 4.4. Checking the hypothesis about the presence of autocorrelation of residuals according to the Durbin - Watson criterion

In the case of the presence of a lagged dependent variable in the model, this criterion is not suitable. We can use the asymptotic Durbin $h$-test. Both of these tests are intended to test autocorrelation of random errors of the first order.

The Von Neumann criterion is determined by the formula:

$$
\begin{equation*}
Q=\frac{\sum_{t=2}^{n}\left(e_{t}-e_{t-1}\right)^{2} / n-1}{\sum_{t=1}^{n}\left(e_{t}\right)^{2} / n}=\frac{n}{n-1} \cdot \frac{\sum_{t=2}^{n}\left(e_{t}-e_{t-1}\right)^{2}}{\sum_{t=1}^{n}\left(e_{t}\right)^{2}} . \tag{38}
\end{equation*}
$$

The value of the Durbin - Watson statistics and the Von Neumann statistics are linked by the ratio: $Q=\frac{n}{n-1} \cdot d$.

If the value of $Q$ is less (or more) than some critical value, then we can speak of positive (or negative) autocorrelation (Fig. 4.5).

| Positive <br> autocorrelation |  | Autocorrelation is absent | Negative <br> autocorrelation |  |
| :--- | :--- | :--- | :--- | :--- |
| 0 | $Q_{c r}^{+}$ |  | $Q_{c r}^{-}$ | $\propto$ |

Fig. 4.5. Verification of the hypothesis about the presence of autocorrelation of residuals by the Von Neumann criterion

So, if $Q_{f a c t}<Q_{c r}^{+}$, then there is a positive autocorrelation, if $Q_{f a c t}>Q_{c r}^{-}$, then there is a negative autocorrelation, and if $Q_{c r}^{+}<Q_{f a c t}<Q_{c r}^{-}$, then the autocorrelation of the residuals is absent.

The cyclic coefficient of autocorrelation expresses the degree of interconnection of the "closed" series of residuals:

1 st series $-e_{1}, e_{2}, e_{3}, \ldots, e_{n-1}, e_{n}$;
2nd series - $e_{2}, e_{3}, e_{4}, \ldots, e_{n}, e_{1}$.
It is calculated by the formula:

$$
\begin{equation*}
r^{0}=\frac{\sum_{t=2}^{n} e_{t} e_{t-1}+e_{n} e_{1}-\frac{1}{n}\left(\sum_{t=1}^{n} e_{t}\right)^{2}}{\sum_{t=1}^{n} e_{t}^{2}-\frac{1}{n}\left(\sum_{t=1}^{n} e_{t}\right)^{2}} . \tag{39}
\end{equation*}
$$

The calculated value of the cyclic coefficient of auto-correlation is compared with the table for the selected level of significance and the length of the row $n$ (Fig. 4.6).

| Negative <br> autocorrelation |  | Autocorrelation is absent | Positive <br> autocorrelation |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| -1 | $-r_{c r}^{-}$ | 0 | $r_{c r}^{+}$ | +1 |

Fig. 4.6. Testing the hypothesis about the presence of autocorrelation of residuals by the cyclic autocorrelation coefficient

If $r_{\text {fact }}>0$ and $r_{\text {fact }} \geq r_{c r}^{+}$, then there is a positive autocorrelation. If $r_{\text {fact }}<0$ and $r_{\text {fact }} \leq r_{c r}^{-}$, then there is a negative autocorrelation.

Assuming that:

$$
\begin{equation*}
\sum_{t=1}^{n} e_{t} \approx \sum_{t=2}^{n} e_{t-1} \approx 0, \tag{40}
\end{equation*}
$$

the cyclic autocorrelation coefficient can be written as:

$$
\begin{equation*}
r^{0}=\frac{n}{n-1} \cdot \frac{\sum_{t=2}^{n} e_{t} e_{t-1}}{\sum_{t=1}^{n}\left(e_{t}\right)^{2}} \tag{41}
\end{equation*}
$$

Let's calculate the value of the Durbin - Watson criterion, the Von Neumann criterion, the cyclic autocorrelation coefficient by the formulas (37) - (41). The results of the interim calculations are shown in Table 4.2.

Table 4.2

## The interim calculations

| No. | $Y$ | $\hat{Y}$ | Residuals, <br> $e_{t}$ | $\left(e_{t}-e_{t-1}\right)^{2}$ | $e_{t}^{2}$ | $e_{t} \cdot e_{t-1}$ |

| 22 | 178.8 | 174.519 | 4.2806 | 178.4778 | 18.3233 | -38.8632 |
| $\Sigma$ | 2287.1 | 2287.1 | 0.0000 | 2397.3662 | 622.8098 | -586.8511 |

As a result of the calculation of the Durbin - Watson criterion, the following result is obtained:

$$
\begin{equation*}
d=\frac{\sum_{t=2}^{n}\left(e_{t}-e_{t-1}\right)^{2}}{\sum_{t=1}^{n} e_{t}^{2}}=\frac{2397.3662}{622.8098} \approx 3.849 . \tag{42}
\end{equation*}
$$

In the Durbin - Watson criterion there are upper and lower limits. For a model with two independent variables and 22 observations, the lower limit $d_{L}=1.15$, the upper limit $d_{U}=1.54$ with the level of significance $0.05 \%$.

Since the calculated value $d$ gets into the interval $4-d_{L} \leq d<4$ $(2.85 \leq d<4)$, then we can conclude that there is a negative autocorrelation of the first order residuals in the model under study.

Let's calculate the Von Neumann statistics:

$$
\begin{equation*}
Q=\frac{n}{n-1} \cdot \frac{\sum_{t=2}^{n}\left(e_{t}-e_{t-1}\right)^{2}}{\sum_{t=1}^{n}\left(e_{t}\right)^{2}}=\frac{n}{n-1} \cdot d=\frac{22}{21} \cdot 3.849=4.03 . \tag{43}
\end{equation*}
$$

The critical values of this criterion for sample size $n=22$ and the level of significance $\alpha=0.05$ are: $Q_{c r}^{+}=1.37$ and $Q_{c r}^{-}=3.12$. Since the value $Q=4.03, Q>3.12$, there is a negative autocorrelation of the residuals.

Let's calculate the cyclic coefficient of autocorrelation:

$$
\begin{equation*}
r^{0}=\frac{n}{n-1} \cdot \frac{\sum_{t=2}^{n} e_{t} e_{t-1}}{\sum_{t=1}^{n}\left(e_{t}\right)^{2}}=\frac{22 \cdot(-586.8511)}{21 \cdot 622.8098}=-0.987 \tag{44}
\end{equation*}
$$

The obtained value $r_{\text {fact }}<0$. The critical value for negative autocorrelation for the sample size $n=22$ and the significance level $\alpha=0.05$ is: $r_{c r}^{-}=0.399$. Since $|-0.987|>0.399$, there is a negative autocorrelation of the residuals.

All three criteria bring us to the same conclusion.
In the case the hypothesis about the presence of autocorrelation is confirmed and the residuals can be represented as the first order autoregressive scheme, the Aitken method (GLSM) should be used to evaluate the model parameters. If the residuals can be represented as a higher order autoregressive scheme, the Cochrane - Orcutt and the Durbin methods are used.

## 3. Testing the heteroscedasticity of the residuals.

One of the important assumptions in constructing a regression model is that random errors in the model are uncorrelated with each other and have a constant variance. This requirement when using the usual least squares method for estimating the parameters of a general linear econometric model is called homoscedasticity. In practice, the requirement of a constant variance of random errors is often not fulfilled, and this phenomenon is called heteroscedasticity. When using a conventional OLS, the presence of heteroscedasticity of residuals will lead to a situation, when the model parameter estimates will be shifted, grounded, but ineffective.

Let's test the residual for heteroscedasticity.
The tests that can detect the presence of heteroscedastic residuals, include the Park, Glaser, White tests. These tests assume that the variability of random residuals is a function of dependence on some factor (or factors).

For the Park test, this dependence is as follows:

$$
\begin{equation*}
\ln e_{i}^{2}=a+b \ln x_{i j}+v_{i}, \tag{45}
\end{equation*}
$$

where $x_{i j}$ is the value $i$ for factor $j$;
$v_{i}$ is the random residual.

The Glaser test should be used to find the parameters of a series of equations given by the function:

$$
\begin{equation*}
\left|e_{i}\right|=a+b x_{i j}^{k}+v_{i}, \tag{46}
\end{equation*}
$$

where $k$ is any number. For example, $k=-1 ;-0.5 ; 0.5 ; 1$, etc.

The White test is based on constructing a quadratic function that includes all factors, as well as their pairwise products. In particular, for a case with two factors, this function will have the form:

$$
\begin{equation*}
e_{i}^{2}=a+b_{11} x_{1 i}+b_{12} x_{1 i}^{2}+b_{21} x_{2 i}+b_{22} x_{2 i}^{2}+c_{12} x_{1 i} x_{2 i}+v_{i} . \tag{47}
\end{equation*}
$$

The residuals are considered heteroscedastic if the parameter $b$ in the functions of the Park test (45) or the Glaser test (46) is statistically significant (for the Glaser test - at least at one $k$ value). While conducting the White test, the heteroscedasticity of random residuals is given if the entire function (47) is significant by the Fisher's criterion $F$.

Let's calculate the values of dependent and independent variables of the functions (45) - (47). The results of the interim calculations are shown in Table 4.3.

Table 4.3

Let's test the residual for heteroscedasticity with the Park test (see formula (45)) for $x_{1}$. We find the parameters of the regression equation using the Data Analysis add-in, the Regression tab, as shown in Fig. 4.7.

Fig. 4.7. Calculation of regression parameters for the Park test
The results of the regression analysis are shown in Fig. 4.8.

Fig. 4.8. The results of the regression analysis

Thus, the following regression equation is obtained:

$$
\begin{equation*}
\ln e^{2}=-4.22+1.88 \ln x_{1}+v ; \quad t_{b}=7.6 \tag{48}
\end{equation*}
$$

Find the table value of Student's criterion, as shown in Fig. 4.9.

Fig. 4.9. Determination of the critical value of Student's criterion
Comparison of the calculated value of Student's criterion $t_{b}=7.6$ and $t_{\text {tab }}=2.09$ (Fig. 4.9) allows us to conclude that the parameter $b$ is statistically significant, that is, the residuals of the model are heteroscedastic.

Similarly, we find the regression equation (45) for the Park test for the variable $x_{2}$, as well as the regression equation (46) by the Glaser test, the regression equation (47) by the White test. Below are the results of the regression analysis.

By the Park test:

$$
\begin{equation*}
\ln e^{2}=-12.37+2.43 \ln x_{2}+v ; \quad t_{b}=2.45 \tag{49}
\end{equation*}
$$

According to the Glaser test, with $k=1$ :

$$
\begin{array}{ll}
|e|=0.5894+0.0858 \cdot x_{1}+v ; & t_{b}=6.91 . \\
|e|=1.122+0.0067 \cdot x_{2}+v ; & t_{b}=1.77 . \tag{51}
\end{array}
$$

By the White test:

$$
\begin{gather*}
e^{2}=-128.595-0.552 \cdot x_{1}+0.023 \cdot x_{1}^{2}+0.485 \cdot x_{2}- \\
-0.0003 \cdot x_{2}^{2}-0.0014 \cdot x_{1} x_{2}+v,  \tag{52}\\
F=23.665 .
\end{gather*}
$$

On the basis of the built-in function of Excel, we find the tabular value of Fisher's criterion, as shown in Fig. 4.10.

Fig. 4.10. Determination of the critical value of Fisher's criterion
The regression equation in the White test is significant ( $F_{\text {tab }}=4.35$ ). The parameters of the model in the Park test are significant ( $t_{\text {tab }}=2.09$ ), consequently, we can assert that the residuals are heteroscedastic. In the Glaser test, the parameter for the factor $x_{1}$ is significant, for the factor $x_{2}$ is insignificant, which allows us to conclude that the dispersion of residuals depends on the factor $x_{1}$.

In cases of violated requirements of the OLS concerning the nature of random residuals, namely, the constancy of the dispersion of random residuals, the non-correlation of the residuals among themselves, the generalized least squares method (GLS) is used.

The essence of this method is the elimination of the violation of the prerequisites of the OLS, adjusting the calculations of the parameters of the regression equation, taking into account the values of the covariance matrix of the residuals. Such a correction can be made using the formula:

$$
\begin{equation*}
\hat{a}=\left(X \Omega^{-1 \prime} X\right)^{-1} X^{\prime} \Omega^{-1} Y \tag{53}
\end{equation*}
$$

where $\Omega$ is the covariance matrix of residuals.

# Practical activity 5. Evaluation and analysis of the main characteristics of the Cobb - Douglas production function 

The goal of the study is to consolidate the theoretical material and obtain practical skills in assessing and analyzing the main properties and characteristics of the production function for the study of real economic processes.

The results of the population numbers $(L)$, the volume of fixed assets $(F)$, GDP $(Y)$ are given in Table 5.1.

Table 5.1

## The output data

| No. | $X_{1}$, <br> $L$ (thousand people) | $X_{2}$, <br> $F($ bln UAH $)$ | $Y$, <br> GDP (bIn UAH) |
| :---: | :---: | :---: | :---: |
| 1 | 1.3 | 2.2 | 2.15 |
| 2 | 2.5 | 2.6 | 4.41 |
| 3 | 2.7 | 3.3 | 5.54 |
| 4 | 2.9 | 3.6 | 6.69 |
| 5 | 3.5 | 4.6 | 7.48 |
| 6 | 4.5 | 5.2 | 9.56 |
| 7 | 6.1 | 5.8 | 10.62 |
| 8 | 7.2 | 6.2 | 11.94 |
| 9 | 8.6 | 7.5 | 12.02 |
| 10 | 8.4 | 10.8 | 18.51 |

## The task is as follows:

1. Check if there is a non-linear relation between the volume of production and the value of production resources by constructing the Cobb - Douglas production function. Calculate the correlation index. Draw a conclusion concerning the adequacy of the non-linear econometric model.
2. Determine the characteristics of the production function (the average and marginal resource productivity, the elasticity of the product output based on the factors and the total elasticity, the capital-labour ratio).
3. Construct the isoquants of the production function, calculate the marginal norms of the substitution of resources at a given point on the isoquants. Draw conclusions.

## Guidelines

The production function (PF) is a function in which the independent variable takes the value of the amount of the consumed or used resource (the factor of production), and the dependent variable is the value of the output volumes.

Production functions include modeling the dependencies that exist between the indicators of production activity, such as the volume of the output, the production costs, the capital expenditures, the capital productivity.

It is assumed that the output factors are the main productive assets $X_{1}$ and labour resources $X_{2}$.

The production function of Cobb - Douglas is an example of a concrete form of a two-factor function:

$$
\begin{equation*}
Y=a_{0} \cdot X_{1}^{a_{1}} \cdot X_{2}^{a_{2}}, \tag{54}
\end{equation*}
$$

where $a_{0}, a_{1}$ and $a_{2}$ are the parameters of the model.

1. Constructing the Cobb - Douglas production function. To linearize the linear dependence to evaluate the parameters of the PF of CobbDouglas the following formula is used:

$$
\begin{equation*}
\ln Y=\ln a_{0}+a_{1}^{*} X_{1}+a_{2}^{*} X_{2} \tag{55}
\end{equation*}
$$

Replace $\ln Y$ with $Z, \ln a_{0}$ with $a_{0}^{*}, \ln X_{1}$ with $Z_{1}, \ln X_{2}$ with $Z_{2}, a_{0}$ with, $e^{a_{0}^{*}}$, $Z=a_{0}^{*}+a_{1}^{*} Z_{1}+a_{2}^{*} Z_{2}$.

The sequence of calculation of the model parameters $Z=a_{0}^{*}+a_{1}^{*} Z_{1}+a_{2}^{*} Z_{2}$ in Excel is shown in Fig. 5.1.

When calculating the model parameters, the following built-in Excel functions are used: $\operatorname{MMULT}($ ), $\operatorname{MINVERSE}()$. Based on the data shown in Fig. 5.1, the parameters of the model $Z=a_{0}^{*}+a_{1} \cdot Z_{1}+a_{2} \cdot Z_{2}$ are equal to $a_{0}^{*}=0.42 ; a_{1}=0.52 ; a_{2}=0.57$. That is, the modified model has the form: $Z=0.42+0.52 \cdot Z_{1}+0.57 \cdot Z_{2}$. A similar result can be obtained using the Data Analysis add-in, the Regression tab, as shown in Fig. 5.2.

Step 1.

Fig. 5.3. The results of the regression analysis
The reverse transition to the nonlinear form of the model is performed $a_{0}^{*}=\ln a_{0} \rightarrow a_{0}=e^{a_{0}^{*}}=e^{0.42}=1.52$ based on the built-in function $\operatorname{EXP}()$.

Thus, the constructed model of the production function of Cobb - Douglas has the form:

$$
\begin{equation*}
Y=1.52 \cdot L^{0.52} K^{0.57} . \tag{56}
\end{equation*}
$$

The quality of the resulting model is assessed based on the index of correlation. The results of the interim calculations are shown in Table 5.2.

Table 5.2

## The interim calculations

| No. | $\hat{y}$ | $\left(y_{i}-\hat{y}_{i}\right)^{2}$ | $\left(y_{i}-\bar{y}_{i}\right)^{2}$ |
| :---: | :---: | :---: | :---: |
| 1 | 2.75 | 0.36 | 45.45 |
| 2 | 4.26 | 0.02 | 20.09 |
| 3 | 5.08 | 0.21 | 11.24 |
| 4 | 5.54 | 1.31 | 4.85 |
| 5 | 7.04 | 0.19 | 1.99 |
| 6 | 8.62 | 0.89 | 0.45 |
| 7 | 10.76 | 0.02 | 2.99 |
| 8 | 12.19 | 0.06 | 9.29 |
| 9 | 14.92 | 8.40 | 9.78 |
| 10 | 18.17 | 0.12 | 92.51 |
| $\Sigma$ | - | 11.59 | 198.63 |

The correlation index is:

$$
\begin{equation*}
R=\sqrt{1-\frac{\sum_{i=1}^{10}\left(Y_{i}-\hat{Y}_{i}\right)^{2}}{\sum_{i=1}^{10}\left(Y_{i}-\bar{Y}\right)^{2}}}=\sqrt{1-\frac{11.59}{198.63}}=0.94 . \tag{57}
\end{equation*}
$$

The value of the correlation index which is equal to 0.94 , allows us to draw a conclusion about the statistical significance of the model and the possibility of using it for further analysis.
2. Calculation of the characteristics of the production function at the point ( $L_{0}=100, K_{0}=100$ ).
2.1. The value of the output for initial conditions with $L_{0}=100, K_{0}=100$ is calculated as:

$$
\begin{equation*}
Y=1.52 \cdot 100^{0.52} \cdot 100^{0.57}=230.06 \tag{58}
\end{equation*}
$$

2.2. The average productivity of resources which shows the average number of products per unit of the spent labor is calculated according to the formula:

$$
\begin{gather*}
A_{1}=\frac{y}{x_{1}}=a_{0} \cdot x_{1}^{a_{1}-1} \cdot x_{2}^{a_{2}} ;  \tag{59}\\
A_{1}=1.52 \cdot 100^{0.52-1} \cdot 100^{0.57}=2.3 . \tag{60}
\end{gather*}
$$

The average return on capital (the capital productivity) shows the volume of products per unit of the used production assets:

$$
\begin{gather*}
A_{2}=\frac{y}{x_{2}}=a_{0} \cdot x_{1}^{a_{1}} \cdot x_{2}^{a_{2}-1} ;  \tag{61}\\
A_{2}=1.52 \cdot 100^{0.52} \cdot 100^{0.57-1}=2.3 . \tag{62}
\end{gather*}
$$

Consider the geometric content of this characteristic. The average productivity of the resource is equal to the tangent of the angle of inclination of the chord, to the abscissa axis (Fig. 5.4), i.e. $A=\operatorname{tg} \alpha, \alpha=\operatorname{arctg} A$.
2.3. The marginal productivity of resources shows how many additional units of production an additional unit of the spent labor brings. It is calculated according to the formula:

$$
\begin{gather*}
M_{1}=\frac{\partial y}{\partial x_{1}}=a_{0} \cdot a_{1} \cdot x_{1}^{a_{1}-1} \cdot x_{2}^{a_{2}} ;  \tag{63}\\
M_{1}=\frac{\partial y}{\partial x_{1}}=1.52 \cdot 0.52 \cdot 100^{0.52-1} \cdot 100^{0.57}=1.2 . \tag{64}
\end{gather*}
$$

Fig. 5.4. The graph of the resource average productivity

The marginal return on capital (the capital outflow) shows how many additional units of production an additional unit of fixed assets brings.

$$
\begin{gather*}
M_{2}=\frac{\partial y}{\partial x_{2}}=a_{0} \cdot a_{2} \cdot x_{1}^{a_{1}} \cdot x_{2}^{a_{2}-1} ;  \tag{65}\\
M_{2}=\frac{\partial y}{\partial x_{1}}=1.52 \cdot 0.57 \cdot 100^{0.52} \cdot 100^{0.57-1}=1.31 . \tag{66}
\end{gather*}
$$

Consider the geometric content of this characteristic. The marginal efficiency (the productivity) of the resource is equal to the tangent of the angle of the tilt in the graph of the PF at the point $x_{0}$ to the axis of abscissa (Fig. 5.5), i.e. $M=\operatorname{tg} \varphi, \varphi=\operatorname{arctg} M$.

### 2.4. The elasticity of the production output as to the factors of production.

The elasticity of the production output in terms of labor costs shows how much the product output will increase with an increase in labor costs by $1 \%$. It can be defined as follows:

$$
\begin{gather*}
E_{1}=\frac{\partial y}{\partial x_{1}} \cdot \frac{x_{1}}{y} ; \quad E_{1}=\frac{M_{1}}{A_{1}} ; \quad E_{1}=a_{1} ;  \tag{67}\\
E_{1}=\frac{1.2}{2.3}=0.52 ; \quad a_{1}=0.52 . \tag{68}
\end{gather*}
$$

Fig. 5.5. The graph of the marginal efficiency of the resource
The elasticity of the production output in terms of the cost of production assets shows how much the percent of the production output will increase with an increase in fixed assets by 1 \%.

$$
\begin{gather*}
E_{2}=\frac{\partial y}{\partial x_{2}} \cdot \frac{x_{2}}{y} ; \quad E_{2}=\frac{M_{2}}{A_{2}} ; \quad E_{2}=a_{2}  \tag{69}\\
E_{2}=\frac{1.31}{2.3}=0.57 ; \quad a_{2}=0.57 \tag{70}
\end{gather*}
$$

The total elasticity of expenses (labour and capital) shows the effect of simultaneous proportional increase in the amount of labor resources and fixed assets:

$$
\begin{equation*}
E=E_{1}+E_{2}=a_{1}+a_{2}=0.52+0.57=1.09 . \tag{71}
\end{equation*}
$$

The elasticity of the PF in the point $C\left(x_{0} \cdot y_{0}\right)$ in modulus is equal to the ratio of distances in the tangent to the point $C$ with coordinates ( $x_{0}, f\left(x_{0}\right)$ ) to the point of intersection with the axes $Y$ and $X$ (Fig. 5.6).

Fig. 5.6. The elasticity of the production function
2.5. The capital-labour ratio shows how much of the average capital fits to the unit of spent labor and it is calculated according to the formula:

$$
\begin{equation*}
F T=\frac{x_{2}}{x_{1}} \tag{72}
\end{equation*}
$$

$$
\frac{100}{100}=1.52-\frac{1}{0.57 \cdot 230.06}-\frac{1}{0.57 \cdot 100}-\frac{1-0.52}{0.57}=1 .
$$

It should be noted that if the sum of indicators in the PF of Cobb Douglas $Y=a_{0} \cdot X_{1}^{a_{1}} \cdot X_{2}^{a_{2}}$ is equal to one, $\left(a_{1}+a_{2}=1\right)$, then we have:

$$
\begin{equation*}
\frac{Y}{x_{1}}=\frac{a_{0} \cdot x_{1}^{a_{1}} \cdot x_{2}^{a_{2}}}{x_{1}}=\frac{a_{0} \cdot x_{2}^{a_{2}}}{x_{1}^{1-a_{1}}}=a_{0} \cdot\left(\frac{x_{2}}{x_{1}}\right)^{a_{2}}, \tag{75}
\end{equation*}
$$

or if we switch to new designations

$$
\begin{align*}
& z=\frac{Y}{x_{1}},  \tag{76}\\
& k=\frac{x_{2}}{x_{1}}, \tag{77}
\end{align*}
$$

then we get the following dependence:

$$
\begin{equation*}
Z=\mathrm{a}_{0} \cdot \mathrm{~K}^{\mathrm{a}_{2}} . \tag{78}
\end{equation*}
$$

Since $0<\mathrm{a}_{2}<1$, the formula implies that the productivity of labor $Z$ is growing more slowly than the capital power.
3. Constructing the isoquants of the production function. The production function allows us to calculate the need for one resource at a given volume of production and the value of another resource.

The need for labor costs with known values of output and capital costs is calculated as:

$$
\begin{equation*}
x_{1}=\left(\frac{\hat{y}}{a_{0} \cdot x_{2}^{a_{2}}}\right)^{\frac{1}{a_{1}}} \tag{79}
\end{equation*}
$$

The need for capital costs with known values of output and labor costs is calculated as:

$$
\begin{equation*}
x_{2}=\left(\frac{\hat{y}}{a_{0} \cdot x_{1}^{a_{1}}}\right)^{\frac{1}{a_{2}}} . \tag{80}
\end{equation*}
$$

The calculation of the need for one of the resources is necessary for the construction of an isoquant of the production function.

The isoquant of the PF is a line of the level $q=f\left(X_{1}, X_{2}\right),(q>0)$, that representing a set of points in which the PF takes the value equal to $q$. The isoquants represent different sets (the ratio) of used resources that provide the same amount of the production output. The graph of the production function isoquant is shown in Fig. 5.7.

Fig. 5.7. The isoquants of the production function
To construct an isoquant of the PF for the production volume $Y=800$, we lave to change the value of the amount of the spent capital (Table 5.3) to calculate the need for labor costs and get the following combinations:

$$
\begin{equation*}
x_{1}=\left(\frac{800}{1.52 \cdot x_{2}^{0.57}}\right)^{\frac{1}{0.52}} \tag{81}
\end{equation*}
$$

Table 5.3

## The need for labor costs

| $X_{1}$ | 100 | 200 | 300 | 400 | 500 | 600 | 700 | 800 | 900 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $X_{2}$ | 1099 | 514 | 330 | 240 | 188 | 154 | 130 | 112 | 99 |

For a given isoquant, construct an isoclinal of the PF, i.e. a line that connects the origin of the coordinates and the points on the isoquants of the PF for which the marginal rates of substitution of resources will be equal (Fig. 5.8).

Fig. 5.8. The isoquant of the PF and the isoclinal
The limit rate of replacement of the $i$-th resource by the $j$-th resource is calculated as follows:

$$
\begin{align*}
R_{i j} & =-\frac{\Delta x_{j}}{\Delta x_{i}},  \tag{82}\\
R_{i j}^{\prime} & =-\frac{\partial x_{j}}{\partial x_{i}} . \tag{83}
\end{align*}
$$

The marginal rate of replacement of resources $R_{i j}$ shows by how many units the costs of the resource $j$ (with a constant fixed output), will increase if the costs of the $i$-th resource decreases by one unit.

For a two-factor production function, the following equality holds:

$$
\begin{gather*}
\left|R_{12}\right|=\frac{E_{1}}{E_{2}} \cdot \frac{x_{2}}{x_{1}} .  \tag{84}\\
\left|R_{12}\right|=\frac{0.52}{0.57} \cdot \frac{240}{400}=0.54 . \tag{85}
\end{gather*}
$$

The marginal rate of replacement of the resource coincides with the tangent of the angle of inclination $f$ to the axis of the tangent to the isoquant VF in the point ( $\left.x_{0}, f\left(x_{0}\right)\right) R_{12}=\operatorname{tg}(\alpha)$.

The production function can be used to calculate the elasticity of the substitution of factors (resources):

$$
\begin{equation*}
\sigma_{i j}=\frac{\partial\left(\frac{x_{j}}{x_{i}}\right)}{\frac{x_{j}}{x_{i}}}: \frac{\partial R_{i j}}{R_{i j}} \tag{86}
\end{equation*}
$$

The elasticity of substitution of resources has the following economic content: it approximately shows how much the percentage of resources should change (with the fixed output), with the marginal replacement rate $R_{i j}$ change by $1 \%$.

## Practical activity 6. Dynamic econometric models

The goal is to consolidate the theoretical material and to acquire the skills in modeling and analysis of dynamic econometric models for the research in real economic processes.

The following data on the dynamics of sales volume are given in Table 6.1.
Table 6.1
The input data

| No. | Date | Sales | No. | Date | Sales |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | November 19, 2014 | 127.96 | 15 | December 7, 2014 | 131.7 |
| 2 | November 20, 2014 | 127.9 | 16 | December 10, 2014 | 132.49 |
| 3 | November 21, 2014 | 128.37 | 17 | December 11, 2014 | 132.45 |
| 4 | November 22, 2014 | 130.1 | 18 | December 12, 2014 | 131.72 |
| 5 | November 23, 2014 | 129.66 | 19 | December 13, 2014 | 131.38 |
| 6 | November 26, 2014 | 128.79 | 20 | December 14, 2014 | 132.37 |
| 7 | November 27, 2014 | 129.83 | 21 | December 17, 2014 | 133.51 |
| 8 | November 28, 2014 | 130.23 | 22 | December 18, 2014 | 132.53 |
| 9 | November 29, 2014 | 130.22 | 23 | December 19, 2014 | 133.13 |
| 10 | November 30, 2014 | 129.66 | 24 | December 20, 2014 | 131.92 |
| 11 | December 3, 2014 | 129.52 | 25 | December 21, 2014 | 131.39 |
| 12 | December 4, 2014 | 130.43 | 26 | December 24, 2014 | 131.15 |
| 13 | December 5, 2014 | 130.58 | 27 | December 25, 2014 | 130.95 |
| 14 | December 6, 2014 | 131.54 | 28 | December 26, 2014 | 129.38 |

According to these data:

1. Build a graph of the dynamics of the indicator and analyse the behaviour of change in its values.
2. Test the availability of a trend in the variance and the mean with Fisher's test, the method of comparison of means and the method of Foster - Stewart.
3. Suggest the hypotheses about the type of trend. Build graphs and estimate the parameters of each trend.
4. Calculate the predicted values of the indicator two steps forward using the model of the time series trend.
5. Provide quality estimates of various models of the trend (the mean error, the mean absolute error, the standard deviation of errors, the mean percentage error, the mean absolute percentage error). Make comparative analysis of the models and determine the most adequate one among them.
6. Provide economic interpretation of the results.

## Guidelines

Starting Microsoft Excel and preparing data. Select MS Excel in the program menu. After its launch, enter the input data, as shown in Fig. 6.1.

1. Building the graph. For plotting, select $\mathrm{C} 1: \mathrm{C} 29$ cells with the input data along with the "Sales" headline and select Plot (Plot with Markers) in the menu item Insert. The result is shown in Fig. 6.2.
2. Testing the trend availability. The preliminary stage of selection of the trend of the time series data is testing the hypothesis about the trend availability in the tested process. The most reliable results can be obtained by applying the Fischer's criterion, the Student's criterion and the method of Foster - Stewart.

The Fisher's test is used to determine the trend in the variance.
The input time series $y_{1}, y_{2}, \ldots, y_{n}$ is split into two volumes of $n_{1}$ and $n_{2}\left(n_{1} \approx n / 2, n_{2}=n-n_{1}\right)$ :

$$
\begin{gather*}
y_{1}, y_{2}, \ldots, y_{k},  \tag{87}\\
y_{k+1}, y_{k+2}, \ldots, y_{n} . \tag{88}
\end{gather*}
$$

In this case: $n_{1}=\frac{28}{2}=14, \quad n_{2}=28-14=14$.
The result is shown in Fig. 6.3.

| $n_{i}$ | 14 | 14 |  |
| $n_{i}-1$ | 13 | 13 |  |

Fig. 6.5. The results of the calculation

The estimated value of the Fisher's test is determined by the formula:

$$
F_{\text {theor }}=\left\{\begin{array}{lll}
\frac{S_{2}^{2}}{S_{1}^{2}}, & \text { if } & S_{2}^{2}>S_{1}^{2}  \tag{89}\\
\frac{S_{1}^{2}}{S_{2}^{2}}, & \text { if } & S_{1}^{2}>S_{2}^{2}
\end{array} .\right.
$$

In this case $S_{1}^{2}>S_{2}^{2}$, thus $F_{c a / c}=E 18 / F 18$.

This value is compared with the tabular one for the significance level $\alpha=0.05$, and the degrees of freedom $k_{1}=n_{1}-1$ and $k_{2}=n_{2}-1$ (where $k_{1}$ corresponds to the bigger variance). Tabular values can be calculated by the formula: $\operatorname{FINV}(0,05 ; E 20 ; F 20)$. The results of the calculation are shown in Fig. 6.6.

Fig. 6.6. The results of the calculation

If $F_{\text {calc }} \geq F_{\text {tab/ }}\left(\alpha, k_{1}, k_{2}\right)$, then the hypothesis about the trend in the variance is confirmed. In this case, $F_{\text {calc }}<F_{\text {tabl }}\left(\alpha, k_{1}, k_{2}\right)$, thus the hypothesis about the trend in the variance is not confirmed, and it can be assumed that this trend in the time series is missing.

After analyzing the availability of a trend in the variance, we proceed to the analysis of the availability of a trend in the mean value using the method of mean comparison.

For this purpose, we calculate the value of $t_{c a l c}$ according to the formula:

$$
\begin{equation*}
t_{c a l c}=\frac{\left|\bar{y}_{1}-\bar{y}_{2}\right|}{\sqrt{\left(n_{1}-1\right) \cdot S_{1}^{2}+\left(n_{2}-1\right) \cdot S_{2}^{2}}} \cdot \sqrt{\frac{n_{1} \cdot n_{2}\left(n_{1}+n_{2}-2\right)}{n_{1}+n_{2}}} . \tag{90}
\end{equation*}
$$

The formulas for calculation are shown in Fig. 6.7.

Fig. 6.7. The formulas for calculation
The estimated value of the Student's $t$-test is compared with the tabular one ( $t_{\text {tabl }}$ ) with a confidence level of $\alpha$ and the number of degrees of freedom $k=n-2$. In this case, $t_{c a l c}>t_{\text {tabl }}$, then the hypothesis about the trend in the mean value is confirmed. And, as $\overline{y_{2}}=\overline{y_{1}}$, the trend is ascending.

The results of the calculation are shown in Fig. 6.8.
Let's consider the use of the method of Foster - Stewart for the same task.

The value of the level $y_{1}$ is called the record one if it is more than any of the previous ones or less than all the previous values.

| 20 | $n_{i}-1$ | 13 | 13 |  |  |

Fig. 6.8. The results of the calculation

The values $u_{i}$ and $v_{i}$ are calculated by the formulas:

$$
\begin{align*}
& u_{i}= \begin{cases}1 & \text { if } y_{i} \text { is less than the previous ones, } \\
0 & \text { otherwise. }\end{cases}  \tag{91}\\
& v_{i}= \begin{cases}1 & \text { if } y_{i} \text { is less than the previous ones }, \\
0 & \text { otherwise } .\end{cases} \tag{92}
\end{align*}
$$

To do this, we create a table header in cells I1, J1, K1, L1. In line with the number 2 dashes should be put.

In the third line, the formula is entered into cell 13 : $=\operatorname{IF}(\mathrm{C} 3=\mathrm{MAX}(\$ \mathrm{C} \$ 2: \mathrm{C} 3) ; 1 ; 0)$. In this formula, only the beginning of the range is "fixed". Then the formula is extended down to the 28th element.

In the next column $J$ in cell J 3 , a similar formula (=IF(C3=MIN(\$C\$2:C3);1;0) is entered and extended down.

The formulas for calculating are shown in Fig. 6.9.

| 4 | I | 」 | K | L |

Fig. 6.9. The formulas for calculation
Next, the values $s_{i}=u_{i}+v_{i}$ and $d_{i}=u_{i}-v_{i}$, are calculated as well as:

$$
\begin{equation*}
S=\sum_{i=2}^{n} s_{i}, \quad D=\sum_{i=2}^{n} d_{i} . \tag{93}
\end{equation*}
$$

For each of these indicators, the value of the Student's t -test is calculated according to the formulas:

$$
\begin{equation*}
t_{D}=\frac{|D|}{\sigma_{D}(n)}, \quad t_{S}=\frac{S-\mu(n)}{\sigma_{S}(n)}, \tag{94}
\end{equation*}
$$

where $\mu(n), \sigma_{S}(n), \sigma_{D}(n)$ are table values.
The calculated values of the Student's t-test are compared with the tabular ones with the confidence level $\alpha$ and the number of degrees of freedom $k=n-2$.

While using the method of Foster - Stewart the following situations may occur:
a) $t_{D}>t_{p}, t_{S}>t_{p}$ - the hypothesis about the trend availability in the mean value is accepted, while if $D>0$, the trend is ascending, and if $D<0$, the trend is descending (in this case, the series monotonically ascends or descends);
b) $t_{D}<t_{p}, t_{S}>t_{p}$ - the hypothesis about the trend availability in the variance is accepted (in this case, the fluctuations of the indicator occur);
c) $t_{D}>t_{p}, t_{S}<t_{p}$ - the hypothesis about the trend availability in the variance or in the mean value cannot be accepted or rejected;
d) $t_{D}<t_{p}, t_{S}<t_{p}$ - the hypothesis about the trend absence both in the variance and the mean value can be accepted.

## 3. Selection of the type of trend.

The data line on the plot should be clicked on with the right mouse button and Add trend line... selected as shown in Fig. 6.10.

Fig. 6.10. Adding the trend line
It is necessary to choose the type of the trend line (e.g., Linear), set the forecast horizon (e.g., 2 periods forward), tick show the equation on the plot, and put the value of approximation reliability on the plot as shown in Fig. 6.11.

Then consequently try alternative types of trend.

Fig. 6.11. Selection of parameters of the trend line
The results of building various trends are shown in Fig. 6.12-6.17.

Fig. 6.12. The results of building the linear trend

Fig. 6.13. The results of building the exponential trend

Fig. 6.14. The results of building the logarithmic trend

Fig. 6.15. The results of building the polynomial trend of the 2nd degree

Fig. 6.16. The results of building the polynomial trend of the 3rd degree

Fig. 6.17. The results of building the polynomial trend of the 4th degree

## 4. Forecasting.

According to the given trend equations, the theoretic values of the sales volume should be calculated ( $\operatorname{Predict}(\hat{y})$ ).

## 5. Quality estimates of various models of the trend.

To explore such quality estimates of the time series model as the mean error, the mean absolute error, the standard deviation of errors, the mean percentage error, the mean absolute percentage error, a new Residuals (Model errors) variable should be entered and calculated by setting the formula Residuals = Sales Volume - Predict.

The formulas for calculating the estimates of the model accuracy are shown in Table 6.2.

Table 6.2

## The characteristics of the estimation of the model accuracy

| Name | Formula |
| :---: | :---: |
| Mean error | m.e. $=\frac{\sum_{t=1}^{n} e_{t}}{n}$ |
| Mean absolute error | m.a.e. $=\frac{\sum_{t=1}^{n}\left\|e_{t}\right\|}{n}$ |
| Sum of squares of errors | s.s.e. $=\sum_{t=1}^{n} e_{t}^{2}$ |
| Mean squared error | m.s.e. $=\sqrt{\frac{\sum_{t=1}^{n} e_{t}^{2}}{n}}$ |
| Mean percentage error | m.p.e. $=\frac{1}{n} \sum_{t=1}^{n} \frac{e_{t}}{y_{t}} \cdot 100 \%$ |
| Mean absolute percentage error | m.a.p.e. $=\frac{1}{n} \sum_{t=1}^{n} \frac{\left\|e_{t}\right\|}{y_{t}} \cdot 100 \%$ |

Draw a comparison of the models for the value of the average absolute percentage error. If the value of the average absolute percentage error is in the range:
$0<m . a . p . e<10 \%$, the model provides a high prediction accuracy;
$10 \%<$ m.a.p.e < $20 \%$, the model provides a satisfactory accuracy of the forecast;
m.a.p.e $>20 \%$, the model is not adequate.

## Content

The general information ..... 3
Content module 1. The basics of econometric modeling ..... 4
Practical activity 1. Preliminary analysis of baseline data ..... 4
Practical activity 2. Modelling and analysis of simple linear econometric models ..... 19
Practical activity 3. Building and analysis of multiple linear econometric models. Multicollinearity ..... 30
Content module 2. Applied econometrics ..... 42
Practical activity 4. Testing of the residuals for autocorrelation and heteroscedasticity ..... 42
Practical activity 5. Evaluation and analysis of the main characteristics of the Cobb - Douglas production function ..... 55
Practical activity 6. Dynamic econometric models ..... 66
Recommended literature ..... 79
11.1. Basic ..... 79
11.2. Additional ..... 79
11.3. Information resources ..... 80
11.4. Methodical support ..... 80

## НАВЧАЛЬНЕ ВИДАННЯ

## ЕКОНОМЕТРИКА

# Практикум для студентів усіх спеціальностей першого (бакалаврського) рівня 

(англ. мовою)

## Самостійне електронне текстове мережеве видання

# Укладачі: Гур'янова Лідія Семенівна Прокопович Світлана Валеріївна Мілевський Станіслав Валерійович 

Відповідальний за видання Т. С. Клебанова

Редактор З. В. Зобова

Коректор З. В. Зобова

Розглянуто основні питання аналізу та прогнозування соціально-економічних і фінансових процесів і систем на основі застосування економетричних методів і моделей. Наведено практикум з навчальної дисципліни за допомогою програми Microsoft Excel.

Рекомендовано для студентів усіх спеціальностей.

План 2018 р. Поз. № 297 ЕВ. Обсяг 82 с.
Видавець і виготовлювач - ХНЕУ ім. С. Кузнеця, 61166, м. Харків, просп. Науки, 9-А
Свідоцтво про внесення суб'єкта видавничої справи до Державного реєстру ДК № 4853 від 20.02.2015 р.
